

Assignment 2B Approach

Task

The problem for this assignment is straightforward, namely analyze the performance of a binary classification model. This model takes in an observation about penguins and then predicts if the penguin is a male or female. The analysis of this model will be checking error rates, testing confusion matrices, finding performance metrics, and discovering threshold use cases.

Challenges

I feel like this assignment, while more involved, is the one I'm more excited for this week. I have more of a mathematical than computer programming background so this lets me flex a muscle I've not used in a while. Since I am new machine learning, I will be following the additional instructions.
